System-wide changes

Release Notes Version 7.4

Discontinuations

From Version 7.4 onwards: Basic Authentication

Please note Basic Authentication is discontinued starting with version 7.4. Until now, HTTP Basic Authentication with login and password has been used for access via API. For security reasons, the authentication mechanism will be switched to the OAuth2 standard in Version 7.4. Authentication via the previously used mechanism will then no longer be possible. For this reason, you should switch your authentication to the new mechanism in the coming months. Note that authentication with the oAuth2 standard was already successfully implemented in version 7.0, so you can start migration right away. For this purpose, the customer application must be registered in the BrandMaker Administration with the HTTP Bearer Authentication and a corresponding oAuth2 workflow. For more information on configuring the authentication, see here.
